

# Foreword

## How Forecasts Are Made

Most of the annual streamflow in the Western United States originates as snowfall. This snowfall accumulates high in the mountains during winter and early spring. As the snowpack accumulates, hydrologists estimate the runoff that will occur when it melts. Predictions are based on careful measurements of snow water equivalent at selected index points. Precipitation, temperature, soil moisture and antecedent streamflow data are viewed in conjunction with snowpack data to prepare runoff forecasts. This report presents a comprehensive picture of water supply outlook conditions for areas dependent upon surface runoff. It includes selected streamflow forecasts, summarized snowpack and precipitation data, reservoir storage data and narratives describing current conditions.

Streamflow forecasts are cooperatively generated by Soil Conservation Service and National Weather Service hydrologists. Forecasts become more accurate as more data affecting runoff becomes known. For this reason, forecasts are issued that reflect three future precipitation conditions — Below Normal, Average, and Above Normal. These forecasts are termed reasonable minimum, most probable, and reasonable maximum. Actual streamflow can be expected to fall between the lower and upper forecast values eight out of ten years.

Snowpack data are obtained by using a combination of manual and automated measurement methods. Manual readings of snow depth and water equivalent are taken at locations called snow courses on a monthly or semi-monthly schedule during the winter. In addition, snow water equivalent, precipitation, temperature, and other parameters are monitored on a daily basis and transmitted via radio telemetry to central data collection facilities. Both monthly and daily data are used to project snowmelt runoff.

## For More Information

Copies of Monthly Water Supply Outlook Reports and other reports may be obtained from the states listed below. Because of the limited space, snow survey measurements are not published in monthly reports. An annual snow survey data summary is published by the Soil Conservation Service for each of the western states. Historical snow survey data may be obtained at those same offices.

STATE	ADDRESS
Alaska	201 East 9th Ave., Suite 300, Anchorage, AK 99501-3687
Arizona	201 East Indianola, Suite 200, Phoenix, AZ 85012
Colorado (New Mexico)	2490 West 26th Ave., Denver, CO 80211
Idaho	304 North 8th Street, Room 345, Boise, ID 83702
Montana	10 East Babcock, Room 443, Federal Building, Bozeman, MT 59715
Nevada	50 South Virginia Street, Third Floor, Reno, NV 89505
Oregon	1220 Southwest 3rd Ave., 16th Floor, Portland, OR 97204
Utah	4402 Federal Building, 125 South State Street, Salt Lake City, UT 84147
Washington	360 U.S. Court House, Spokane, WA 99201
Wyoming	Federal Building, 100 East "B" Street, Casper, WY 82602

In addition to state reports, a Water Supply Outlook for the Western United States is published by the Soil Conservation Service and National Weather Service monthly, January through May. Reports may be obtained from the Soil Conservation Service, West National Technical Center, 511 Northwest Broadway, Room 547, Portland, OR 97209.

Personnel

## GENERAL OUTLOOK

### SUMMARY:

Snowpack conditions improved over most of the state during February. The southern half of Montana generally has average or a little above average snowpack. The northern half of the state generally has below average snowpack. Also, the Gallatin and parts of the Red Rock, Yellowstone and Musselshell drainages have below average snow cover. February precipitation was above average. Some rain that occurred in northwest Montana passed through the snowpack. Warm temperatures, rain and low elevation snowmelt combined to generate runoff in many areas. Most low elevation snowpack is now gone. Streamflows during the spring and summer months are forecast to be near to a little above average for southern drainages dropping to below average runoff over the remainder of the state.

### SNOWPACK:

February was a good snowfall month. Most areas showed an increase of 10 to 20 percent in snowpack figures over those reported on February 1. The greatest increase was noted in the southern part of the state during the last 2 weeks of February. Most headwaters in southern Montana show near to above average snowpack. Exceptions are the Gallatin and parts of the Red Rock, Musselshell and Yellowstone drainages. Almost all areas in the northern half of the state have below average snowpack with many locations showing less snow than was reported last year at this time. Rain fell in the northern part of Montana near the end of February and passed through the snowpack. Warm temperatures during the last week of the month melted some low and mid-elevation snow and depleted snow from valley areas.

### PRECIPITATION:

February precipitation was above average throughout all mountain ranges in Montana. Some locations recorded as much as two times their average February amounts. Usually precipitation at this time of year falls as snow even in the valley areas. This year, some of the precipitation occurred as rain even in the higher elevations of the northwestern part of the state. In many areas, the rain passed through the snowpack and generated early season runoff.

## RESERVOIRS:

Nelson Reservoir in the Milk River drainage, most reservoirs in the Musselshell River drainage, Smith River Reservoir and Tongue River Reservoir had below average storage on the last day of February. All other irrigation reservoirs have storage levels near or above average. Most multipurpose or hydroelectric reservoirs have near average storage.

## STREAMFLOW:

Streamflow forecasts are based on current snowpack and soil moisture conditions and near average precipitation for the remainder of the season. West of the Divide, most streams and rivers are forecast to have below average spring and summer runoff. The Bitterroot River drainage and adjacent Rock Creek are forecast to flow a little below average. Most streams in the Flathead and Clark Fork River drainages are expected to produce about 80 to 85 percent of average runoff. Smaller streams with lower elevation headwaters in the Kootenai and Clark Fork should have streamflows in the 70 to 80 percent of average range. East of the Divide, forecasts for the Missouri River headwaters vary from near average on the Jefferson, to above average on the Madison and below average on the Gallatin. Runoff from central Montana mountain ranges is expected to be near to a little below average. Streams flowing from the west into the Missouri River downstream from Canyon Ferry Reservoir and those in the St. Mary drainage are expected to produce only 75 to 85 percent of their average runoff. The Yellowstone, Boulder, Stillwater, and Clarks Fork Rivers are forecast to be near average. Downstream, the Bighorn, Little Bighorn, Tongue and Powder Rivers are all forecast to have above average streamflows.

## WATER SUPPLY OUTLOOK:

The mountain snowpack improved slightly during the past month. February precipitation was a little above average but much of it fell as rainfall and passed through the snowpack. Also some snowmelt was noted at lower elevations. Snow conditions are a little better in Canada. There is less snow than last year on the watersheds. Spring and summer streamflows on the Kootenai River are expected to be a little below average. Smaller tributary streams in Montana are expected to have below average runoff.

For more information contact your local Soil Conservation Service office.

## WATER SUPPLY OUTLOOK:

Snowpack has improved slightly during February even though some of the moisture came as rain and passed through the snowpack. Presently, there is less snow than was measured last year on this date. Total precipitation for February was above average. Some runoff has occurred from snowmelt caused by recent warm temperatures and rain. Spring and summer streamflows are predicted to be below average on all drainages.

## WATER SUPPLY OUTLOOK:

Snowpack conditions improved somewhat during February but they are still below average over most of the drainage. February precipitation was well above average. Some runoff was generated from low elevation snowmelt and rainfall during the last week in February. Runoff during spring and summer is forecast to be below average.

For more information contact your local Soil Conservation Service office.

## WATER SUPPLY OUTLOOK:

The Bitterroot snowpack improved significantly during February and is now a little below average. The lower Clark Fork also improved but still has below average snow cover. Precipitation during February was well above average. There has been some runoff from lower elevations because of snowmelt and rain. April through September runoff is forecast at near to a little below average on the Bitterroot streams. Streams flowing into the lower Clark Fork are expected to have below average runoff.

## WATER SUPPLY OUTLOOK:

Snowpacks have improved a little during February but remain well below average in the Bridger Range and on the north end of the Gallatin Range. This area also has less snow than was measured a year ago. Snowpacks are a little better in the southern part of the headwaters but are still below average. February precipitation was a little above average. Spring and summer streamflows are forecast to be below average from all drainages.

For more information contact your local Soil Conservation Service office.

## WATER SUPPLY OUTLOOK:

Snowpack conditions improved during February. Mountain snowpacks are generally near average in the southern part of the drainage but decrease on downstream tributaries. Precipitation during February was above average. Some runoff occurred in late February from low elevation snowmelt and rainfall. Streamflows during the spring and summer period are forecast to vary from near average in the headwaters and tributaries in the southern areas to below average from downstream tributaries.

For more information contact your local Soil Conservation Service office.

## WATER SUPPLY OUTLOOK:

Snowpack improved during February but is still below average in most areas. Also, there is less snow now than was measured a year ago. High elevation snowpacks are a little better than lower and mid-elevation snowpacks. Precipitation during February was well above average. Runoff increased near the end of February from low elevation snowmelt and rainfall. Spring and summer streamflows are forecast to be below average from all drainages.

Precipitation\* (percent of normal)

\*Based on selected stations

## WATER SUPPLY OUTLOOK:

Warm temperatures near the end of February have depleted snowpacks in the Milk River drainage. Snow in the headwaters of the Milk and St. Mary Rivers is well below average even though February precipitation was well above average. Some of the February moisture fell as rain and passed through the snowpack and some melt was noted in lower elevation snowpacks. Streamflows are forecast to be well below average during the spring and summer months.

For more information contact your local Soil Conservation Service office.

## WATER SUPPLY OUTLOOK:

Snowpacks vary from above average in the Yellowstone headwaters to below average in the Bridger and Crazy Mountains. The Tongue, Powder and Bighorn drainages in Wyoming have above to well above average snow. February precipitation was nearly double the average. Spring and summer runoff is forecast above average for tributaries starting in or near Wyoming. Tributaries originating in the Crazy and Bridger Mountains are forecast to have below average streamflows.

For more information contact your local Soil Conservation Service office.
